

## How to Configure & Run the Application

- 1) Install Tomcat server
- 2) Install Lamp server (apache, mysql)
- 3) Configure phpmyadmin
- 4) Install database by running the script "tomcat\_realm.sql" under "assets\db"
- 5) Setup SSL on Tomcat by following the steps in the how-to guide that exists under wiki "How-do-I-set-up-SSL-on-Tomcat.pdf"
- 6) Next, we need to update the Tomcat server.xml file to connect to the MySQL realm database that we just created. we need to comment out the UserDatabase realm section. we will create a JDBC realm entry containing all of the correct information, as shown here:

```
<Realm className="org.apache.catalina.realm.LockOutRealm">

    <!-- This Realm uses the UserDatabase configured in the global JNDI
    resources under the key "UserDatabase". Any edits
    that are performed against this UserDatabase are immediately
    available for use by the Realm. -->

    <!-- <Realm className="org.apache.catalina.realm.UserDatabaseRealm"
    resourceName="UserDatabase"/> -->

</Realm>

<Realm className="org.apache.catalina.realm.JDBCRealm"
digest="MD5"

    driverName="com.mysql.jdbc.Driver"

    connectionURL="jdbc:mysql://localhost:3306/tomcat_realm"

    connectionName="realm_access" connectionPassword="realmpass"

    userTable="tomcat_users" userNameCol="user_name" userCredCol="password"

    userRoleTable="tomcat_users_roles" roleNameCol="role_name" />
```
